Review: Inequalities and Systems of Inequalities
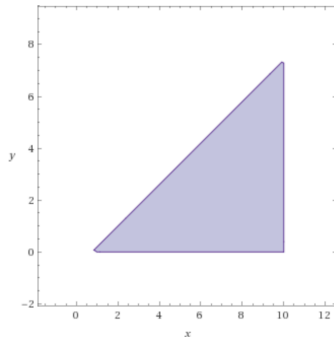

Consider the following inequalities:

1 $4x - 5y > 3$

2 $x + y \geq 2$

3 $3x + 2y < 5$

What is the region of the plane corresponding
to their solution? ($0 \leq x \leq 10,\ 0 \leq y \leq 10$)

1 $4x - 5y > 3 \longrightarrow y < \frac{4}{5}x - \frac{3}{5}$

Consider the following inequalities:

1. $4x - 5y > 3$
2. $x + y \geq 2$
3. $3x + 2y < 5$

What is the region of the plane corresponding to their solution? ($0 \leq x \leq 10$, $0 \leq y \leq 10$)

2. $x + y \geq 2 \longrightarrow y \geq -x + 2$
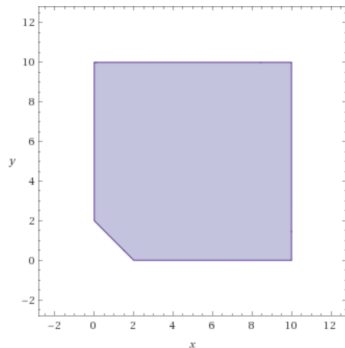

Consider the following inequalities:

1. $4x - 5y > 3$
2. $x + y \geq 2$
3. $3x + 2y < 5$

What is the region of the plane corresponding to their solution? ($0 \leq x \leq 10$, $0 \leq y \leq 10$)

3. $3x + 2y < 5 \longrightarrow y < -\frac{3}{2}x + 5$

Consider now the following systems:

1 $\begin{cases} x + 2y \leq 8 \\ 3x - 5y \leq 13 \\ x \geq 0, \ y \geq 0 \end{cases}$

2 $\begin{cases} 2x + y \leq 7 \\ 4x + 2y \geq 6 \\ x \geq 0, \ y \geq 0 \end{cases}$

What is the region of the plane corresponding
to their solution?

Consider now the following systems:

**1**
$$\begin{cases} x + 2y \leq 8 \\ 3x - 5y \leq 13 \\ x \geq 0, \ y \geq 0 \end{cases}$$

**2**
$$\begin{cases} 2x + y \leq 7 \\ 4x + 2y \geq 6 \\ x \geq 0, \ y \geq 0 \end{cases}$$

What is the region of the plane corresponding to their solution?
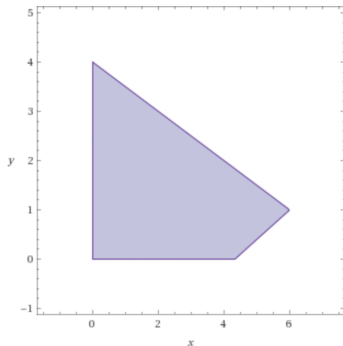

**1** $y \leq -\frac{1}{2}x + 4, \ y \geq \frac{3}{5}x - \frac{13}{5}$

Consider now the following systems:

**1**
$$\begin{cases} x + 2y \leq 8 \\ 3x - 5y \leq 13 \\ x \geq 0, \ y \geq 0 \end{cases}$$

**2**
$$\begin{cases} 2x + y \leq 7 \\ 4x + 2y \geq 6 \\ x \geq 0, \ y \geq 0 \end{cases}$$

What is the region of the plane corresponding to their solution?

**2** $y \leq -2x + 7, \ y \geq -2x + 3$
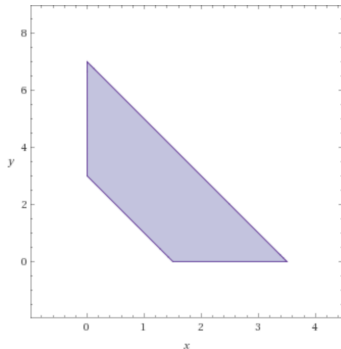

Two more systems with special features:

1 $\begin{cases} x + y > 3 \\ x + y < -1 \end{cases}$

2 $\begin{cases} x + y < 3 \\ x + 2y > 3 \end{cases}$

What is the region of the plane corresponding
to their solution?

---

[1]Examples taken from [1]

Two more systems with special features:

1 $\begin{cases} x + y > 3 \\ x + y < -1 \end{cases}$

2 $\begin{cases} x + y < 3 \\ x + 2y > 3 \end{cases}$

What is the region of the plane corresponding to their solution?

1 $y > -x + 3, \; y < -x + 1$

No Solution

Two more systems with special features:

1 $\begin{cases} x + y > 3 \\ x + y < -1 \end{cases}$

2 $\begin{cases} x + y < 3 \\ x + 2y > 3 \end{cases}$

What is the region of the plane corresponding to their solution?

2 $y < -x + 3, \; y > -\frac{1}{2}x + \frac{3}{2}$

Unbounded Region

Università

Review: Inequalities and Systems of Inequalities

- Solving a system of inequalities in two variables will identify a specific region of the plane.
- However there are some cases in which the system does not admit a solution (no region of the plane can be identified since the constraints are incompatible).
- In another cases we can identify an unbounded region (all the values of the plane are therefore acceptable as possible solutions).
- In these examples we sticked to 2 variables in order to obtain an easy-to-interpret graphical representation. The same concepts will hold however when extending our analysis to multiple dimensions.

- Linear programming is a type of optimization which aims at maximizing or minimizing a given quantity (e.g., find the minimum cost or the maximum profit).
- A linear programming problem consists of a linear objective function:

$$z = c_1 x_1 + c_2 x_2 + \cdots + c_n x_n$$

and a set of constraints given by a system of linear inequalities:

$$a_{1,1} x_1 + a_{1,2} x_2 + \cdots + a_{1,n} x_n \geq h_1$$
$$\vdots$$
$$a_{m,1} x_1 + a_{m,2} x_2 + \cdots + a_{m,n} x_n \leq h_m$$

# Linear Programming

To rewrite our problem in matrix notation, we can start by defining the following quantities:

- $c \in \mathbb{R}^n$ is a vector of coefficients (or weights)
- $A \in \mathbb{R}^{m \times n}$ is the matrix of coefficients of the constraints
- $h \in \mathbb{R}^m$ is the vector of coefficients of the constraints
- $x \in \mathbb{R}^n$ is the vector of unknowns that represent the solution of our problem

By flipping all the inequalities so that we always have an upper bound for the maximization problem and a lower bound for the minimization problem, we can obtain the following **standard form of a linear program**.

Maximum problem:

$$\max \quad z = c^\mathsf{T} x$$
$$\text{s.t.} \quad Ax \le h$$
$$x \ge 0$$

Minimum problem:

$$\min \quad z = c^\mathsf{T} x$$
$$\text{s.t.} \quad Ax \ge h$$
$$x \ge 0$$

Please notice that we have added an additional **non-negativity** constraint ($x \ge 0$).

# Fundamental Theorem of Linear Programming

### Theorem

*If a linear programming problem has a solution, it must occur at a **vertex** of the set of feasible solutions. If the problem has more than one solution, then at least one of them must occur at a vertex of the set of feasible solutions. In either case, the value of the objective function is **unique**.*

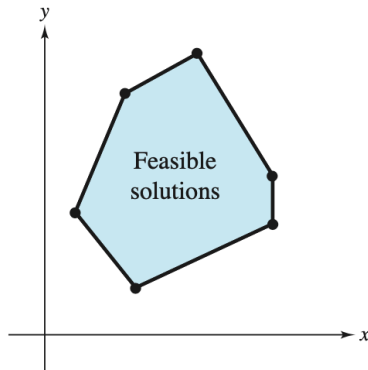

Graphical Solution of a Linear Program

Let us first consider the graphical solution of a linear program in two variables.

1. Solve the system of inequalities given by the constraints.

2. Identify the part of the plane corresponding to the feasible region. All the points inside the feasible region or on its boundary are feasible solutions, but, according to the theorem above, at least one optimal solution must occur at a vertex.

3. Evaluate the objective function at the vertices and pick the one which optimises its value. If the feasible region is bounded, we can find both a minimum and a maximum value.

Let us consider the maximization problem:

$$\begin{aligned}
\max \quad & z = 4x + 6y \\
\text{s.t.} \quad & -x + y \leq 11 \\
& x + y \leq 27 \\
& 2x + 5y \leq 90 \\
& x,\, y \geq 0
\end{aligned}$$

---

[2]The following examples/exercises are taken from [1]

Università
della
Svizzera
italiana

Institute of
Computing
CI

Graphical Solution of a Linear Program: Example 1

Let us consider the maximization problem:

$$
\begin{aligned}
\max \quad & z = 4x + 6y \\
\text{s.t.} \quad & -x + y \leq 11 \\
& x + y \leq 27 \\
& 2x + 5y \leq 90 \\
& x,\, y \geq 0
\end{aligned}
$$

**1** Solve the system of inequalities given by the constraints:

$$
\begin{cases}
-x + y \leq 11 & \longrightarrow y \leq x + 11 \\
x + y \leq 27 & \longrightarrow y \leq -x + 27 \\
2x + 5y \leq 90 & \longrightarrow y \leq -\frac{2}{5}x + 18 \\
x,\, y \geq 0
\end{cases}
$$

# Graphical Solution of a Linear Program: Example 1

Let us consider the maximization problem:

$$
\begin{aligned}
\max \quad & z = 4x + 6y \\
\text{s.t.} \quad & -x + y \leq 11 \\
& x + y \leq 27 \\
& 2x + 5y \leq 90 \\
& x,\, y \geq 0
\end{aligned}
$$

2  The feasible region is given by:

Let us consider the maximization problem:

$$
\begin{aligned}
\max \quad & z = 4x + 6y \\
\text{s.t.} \quad & -x + y \leq 11 \\
& x + y \leq 27 \\
& 2x + 5y \leq 90 \\
& x,\, y \geq 0
\end{aligned}
$$
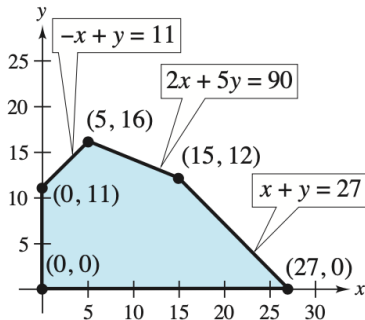

**3** Evaluate the objective function at the vertices and pick the maximum value:

At vertex $(0,0):$ $z = 0$

At vertex $(0,11):$ $z = 66$

At vertex $(5,16):$ $z = 116$

At vertex $(15,12):$ $z = 132$

At vertex $(27,0):$ $z = 108$

The optimal $z^* = 132$ is at vertex $(15, 12)$.

Università
della
Svizzera
italiana

Institute of
Computing
CI

Graphical Solution of a Linear Program: Example 2

Let us consider the minimization problem:

$$
\begin{aligned}
\min \quad & z = 5x + 7y \\
\text{s.t.} \quad & 2x + 3y \geq 6 \\
& 3x - y \leq 15 \\
& -x + y \leq 4 \\
& 2x + 5y \leq 27 \\
& x,\, y \geq 0
\end{aligned}
$$

Let us consider the minimization problem:

$$\begin{aligned}
\min \quad & z = 5x + 7y \\
\text{s.t.} \quad & 2x + 3y \geq 6 \\
& 3x - y \leq 15 \\
& -x + y \leq 4 \\
& 2x + 5y \leq 27 \\
& x,\, y \geq 0
\end{aligned}$$

**1** Solve the system of inequalities given by the constraints:

$$\begin{cases}
2x + 3y \geq 6 & \longrightarrow y \geq -\frac{2}{3}x + 2 \\
3x - y \leq 15 & \longrightarrow y \geq 3x - 15 \\
-x + y \leq 4 & \longrightarrow y \leq x + 4 \\
2x + 5y \leq 27 & \longrightarrow y \leq -\frac{2}{5}x + \frac{27}{5} \\
x,\, y \geq 0 &
\end{cases}$$

Let us consider the minimization problem:

$$\begin{aligned}
\text{min} \quad & z = 5x + 7y \\
\text{s.t.} \quad & 2x + 3y \geq 6 \\
& 3x - y \leq 15 \\
& -x + y \leq 4 \\
& 2x + 5y \leq 27 \\
& x,\, y \geq 0
\end{aligned}$$

**2** The feasible region is given by:

Let us consider the minimization problem:

$$\begin{aligned} \min \quad & z = 5x + 7y \\ \text{s.t.} \quad & 2x + 3y \geq 6 \\ & 3x - y \leq 15 \\ & -x + y \leq 4 \\ & 2x + 5y \leq 27 \\ & x,\, y \geq 0 \end{aligned}$$

3 Evaluate the objective function at the vertices and pick the minimum value:

At vertex $(0,2)$ : $z = 14$
At vertex $(0,4)$ : $z = 28$
At vertex $(1,5)$ : $z = 40$
At vertex $(6,3)$ : $z = 51$
At vertex $(5,0)$ : $z = 25$
At vertex $(3,0)$ : $z = 15$

The optimal $z^* = 14$ is at vertex $(0,2)$.

The liquid portion of a diet is to provide at least 300 calories, 36 units of vitamin A, and 90 units of vitamin C daily. A cup of dietary drink X provides 60 calories, 12 units of vitamin A, and 10 units of vitamin C. A cup of dietary drink Y provides 60 calories, 6 units of vitamin A, and 30 units of vitamin C. Now, suppose that dietary drink X costs \$0.12 per cup and drink Y costs \$0.15 per cup. How many cups of each drink should be consumed each day to minimise the cost and still meet the stated daily requirements?

The liquid portion of a diet is to provide at least 300 calories, 36 units of vitamin A, and 90 units of vitamin C daily. A cup of dietary drink X provides 60 calories, 12 units of vitamin A, and 10 units of vitamin C. A cup of dietary drink Y provides 60 calories, 6 units of vitamin A, and 30 units of vitamin C. Now, suppose that dietary drink X costs $0.12 per cup and drink Y costs $0.15 per cup. How many cups of each drink should be consumed each day to **minimise the cost** and still meet the stated daily requirements?

We obtain the minimization problem:

$$
\begin{aligned}
\min \quad & z = 0.12x + 0.15y \\
\text{s.t.} \quad & 60x + 60y \geq 300 \\
& 12x + 6y \geq 36 \\
& 10x + 30y \geq 90 \\
& x,\, y \geq 0
\end{aligned}
$$

# Formulating a Problem as a Linear Program

We obtain the minimization problem:

$$
\begin{aligned}
\min \quad & z = 0.12x + 0.15y \\
\text{s.t.} \quad & 60x + 60y \geq 300 \\
& 12x + 6y \geq 36 \\
& 10x + 30y \geq 90 \\
& x,\, y \geq 0
\end{aligned}
$$

**1** Solve the system of inequalities given by the constraints:

$$
\begin{cases}
60x + 60y \geq 300 & \longrightarrow y \geq -x + 5 \\
12x + 6y \geq 36 & \longrightarrow y \geq -2x + 6 \\
10x + 30y \leq 90 & \longrightarrow y \geq -\frac{1}{3}x + 3 \\
x,\, y \geq 0
\end{cases}
$$

We obtain the minimization problem:

$$\begin{aligned} \min \quad & z = 0.12x + 0.15y \\ \text{s.t.} \quad & 60x + 60y \geq 300 \\ & 12x + 6y \geq 36 \\ & 10x + 30y \geq 90 \\ & x,\ y \geq 0 \end{aligned}$$

**2** The feasible region is given by:

# Formulating a Problem as a Linear Program

We obtain the minimization problem:

$$\min \quad z = 0.12x + 0.15y$$
$$\text{s.t.} \quad 60x + 60y \geq 300$$
$$12x + 6y \geq 36$$
$$10x + 30y \geq 90$$
$$x, \, y \geq 0$$
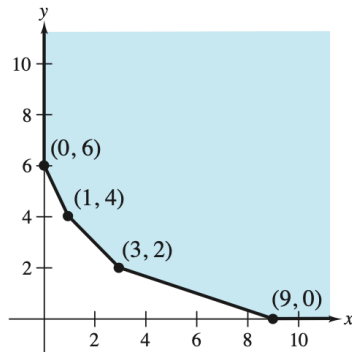

**3** Evaluate the objective function at the vertices and pick the minimum value:

At vertex $(0, 6):\ z = 0.90$

At vertex $(1, 4):\ z = 0.72$

At vertex $(3, 2):\ z = 0.66$

At vertex $(9, 0):\ z = 1.08$

The optimal $z^* = 0.66$ is at vertex $(3, 2)$.

The Simplex Method

- The graphical solution of a linear program can be useful when we have only two variables and we can easily identify both the feasible region (given by the constraints) and the vertices to consider as possible optimal solutions.

- When we have, however, a large number of variables to optimise with several constraints, it is better to adopt a more efficient procedure.

- Here we will consider the simplex method, introduced by Dantzig in 1947.

We consider the maximization of a linear program in standard form and we add $m$ **slack variables** to turn the inequality constraints in equalities, going from:

$$a_{1,1}x_1 + a_{1,2}x_2 + \cdots + a_{1,n}x_n \leq h_1$$
$$\vdots$$
$$a_{m,1}x_1 + a_{m,2}x_2 + \cdots + a_{m,n}x_n \leq h_m$$

to the following new system of constraints:

$$a_{1,1}x_1 + a_{1,2}x_2 + \cdots + a_{1,n}x_n + s_1 = h_1$$
$$\vdots$$
$$a_{m,1}x_1 + a_{m,2}x_2 + \cdots + a_{m,n}x_n + s_m = h_m$$

# Maximization: Introducing the Slack Variables

The quantities will then be redefined as follows (notice the new dimensions except for $h$):

$$
c = \underbrace{\begin{bmatrix} c_1 \\ \vdots \\ c_n \\ 0 \\ \vdots \\ 0 \end{bmatrix}}_{(n+m)\times 1}, \quad
x = \underbrace{\begin{bmatrix} x_1 \\ \vdots \\ x_n \\ s_1 \\ \vdots \\ s_m \end{bmatrix}}_{(n+m)\times 1}, \quad
A = \underbrace{\begin{bmatrix} a_{1,1} & \ldots & a_{1,n} & 1 & 0 & \ldots & 0 \\ a_{2,1} & \ldots & a_{2,n} & 0 & 1 & \ldots & 0 \\ \vdots & \ddots & \vdots & \vdots & \vdots & \ddots & \vdots \\ a_{m,1} & \ldots & a_{m,n} & 0 & 0 & \ldots & 1 \end{bmatrix}}_{m\times(n+m)}, \quad
h = \underbrace{\begin{bmatrix} h_1 \\ \vdots \\ h_m \end{bmatrix}}_{m\times 1}
$$

and we will add the non-negativity constraint also for the slack variables ($s_1, \ldots, s_m \geq 0$).

We consider the minimization of a linear program in standard form and we subtract $m$ **surplus variables** to turn the inequality constraints in equalities, going from:

$$a_{1,1}x_1 + a_{1,2}x_2 + \cdots + a_{1,n}x_n \geq h_1$$
$$\vdots$$
$$a_{m,1}x_1 + a_{m,2}x_2 + \cdots + a_{m,n}x_n \geq h_m$$

to the following new system of constraints:

$$a_{1,1}x_1 + a_{1,2}x_2 + \cdots + a_{1,n}x_n - s_1 = h_1$$
$$\vdots$$
$$a_{m,1}x_1 + a_{m,2}x_2 + \cdots + a_{m,n}x_n - s_m = h_m$$

Università
della
Svizzera
italiana

Institute of
Computing
CI

Minimization: Introducing the Surplus Variables

The quantities will then be given by (notice the sign of A compared to the maximization):

$$
c = \underbrace{\begin{bmatrix} c_1 \\ \vdots \\ c_n \\ 0 \\ \vdots \\ 0 \end{bmatrix}}_{(n+m)\times 1}, \quad x = \underbrace{\begin{bmatrix} x_1 \\ \vdots \\ x_n \\ s_1 \\ \vdots \\ s_m \end{bmatrix}}_{(n+m)\times 1}, \quad A = \underbrace{\begin{bmatrix} a_{1,1} & \ldots & a_{1,n} & -1 & 0 & \ldots & 0 \\ a_{2,1} & \ldots & a_{2,n} & 0 & -1 & \ldots & 0 \\ \vdots & \ddots & \vdots & \vdots & \vdots & \ddots & \vdots \\ a_{m,1} & \ldots & a_{m,n} & 0 & 0 & \ldots & -1 \end{bmatrix}}_{m\times(n+m)}, \quad h = \underbrace{\begin{bmatrix} h_1 \\ \vdots \\ h_m \end{bmatrix}}_{m\times 1}
$$

and we will add the non-negativity constraint also for the surplus variables ($s_1, \ldots, s_m \geq 0$).

# Basic and Nonbasic Variables

- We can freely swap the rows of $A$, as long as we swap also the elements of vector $h$
- We can freely swap the columns of $A$, as long as we swap also the elements of vector $x$
- Matrix $A$ can be split into two sub-matrices as follows:

$$A = \begin{bmatrix} B & D \end{bmatrix}$$

$B \in \mathbb{R}^{m \times m}$ is the matrix formed by $m$ linearly independent columns of $A$ (it has, therefore, full rank and it is invertible). $D \in \mathbb{R}^{m \times n}$ contains the remaining columns.

- In the same way, we can also split $x$ and $c$:

$$x = \begin{bmatrix} x_B \\ x_D \end{bmatrix}, \quad c = \begin{bmatrix} c_B \\ c_D \end{bmatrix}, \quad \text{with } x_B, c_B \in \mathbb{R}^{m \times 1} \text{ and } x_D, c_D \in \mathbb{R}^{n \times 1}$$

Università
della
Svizzera
italiana

Institute of
Computing
CI

Basic and Nonbasic Variables

- We can rewrite our constraints system $Ax = h$ by using the new decomposition:

$$Bx_B + Dx_D = h \longrightarrow Bx_B = h - Dx_D$$

The variables in $x_B$ are called *basic variables*, while those in $x_D$ are *nonbasic variables*.

- By inverting matrix $B$ (always nonsingular since its rank is full) we obtain:

$$x_B = B^{-1}h - B^{-1}Dx_D$$

This represents a general solution of our problem and the value of the basic variables $x_B$ depends on the values assigned to the nonbasic variables $x_D$.

- Please notice that $x_B$ can contain both the original unknowns $(x_1, \ldots, x_n)$ and the slack variables $(s_1, \ldots, s_m)$.

Università
della
Svizzera
italiana

Institute of
Computing
CI

Basic Solutions

- We call *basic solution* the one obtained by setting $x_D = 0$

$$x_B = B^{-1}h$$

  If the non-negativity condition $x_B \geq 0$ is satisfied, then the basic solution is *feasible*.
- In case one or more components of $x_B$ have value 0, the solution is *degenerate*.
- The basic solutions correspond to the vertices of the polytope (the points defined by the intersection of the constraints).

Università
della
Svizzera
italiana | Institute of
Computing
CI

The Simplex Method: Algorithm

---

**Algorithm 1** Simplex Method

---

1: Write the problem in standard form and add slack/surplus variables

2: Consider a feasible starting basic solution (through solution of an *auxiliary problem*)

3: **while** the *optimality criterion* is not satisfied **do**

4:    Apply the *iterative rule* by exchanging one basic and nonbasic variable.

5: **end while**

6: **return** the basic solution satisfying the optimality criterion

---

Università
della
Svizzera
italiana

Institute of
Computing
CI

Existence of an Optimal Basic Solution

- The existence of a feasible solution according to the Fundamental Theorem of Linear Programming implies also the existence of a feasible basic solution. Moreover, the existence of an optimal solution, implies also the existence of an optimal basic solution.
- The simplex method will then iterate through the corners of the polytope delimited by the constraints of the problem, until the optimality criterion is satisfied.
- **Downside:** The number of possible basic solutions grows exponentially with the number of unknowns and constraints. The possible *maximum number of iterations* is given by:

$$N = \frac{(m+n)!}{m!n!}$$

- The optimality condition that needs to be checked at every iteration is based on the **reduced cost coefficients**:

$$r_D = c_D^{\mathsf{T}} - c_B^{\mathsf{T}} B^{-1} D$$

where $c_D$ represents the nonbasic coefficients of the objective function, $c_B$ the basic coefficients of the objective function, $B^{-1}$ the inverse of the basic matrix and $D$ the nonbasic matrix.

- The optimality conditions are given by:

maximization:

$$r_D \leq 0$$

minimization:

$$r_D \geq 0$$

- If the optimality condition is not met, the variable with the highest value of the reduced cost coefficient $r_D$ for a maximization (or the one with the lowest value in case of a minimization) needs to be brought inside the basis.

- The departing variable is determined by taking the ratio:

$$\frac{B^{-1}h}{B^{-1}D} \tag{1}$$

for the column referring to the entering variable and by selecting the variable with the smallest **positive** value.

In order to find a feasible initial basic solution, the two phases method requires the solution of an **auxiliary problem**. The first thing to do is to ensure the positivity of the right hand side: in other words, we want all $h_1, \ldots, h_m$ to be positive. We will then add slack variables or subtract surplus variables to ensure that this condition is met:

$$a_{1,1}x_1 + a_{1,2}x_2 + \cdots + a_{1,n}x_n \pm s_1 = h_1$$
$$\vdots$$
$$a_{m,1}x_1 + a_{m,2}x_2 + \cdots + a_{m,n}x_n \pm s_m = h_m$$

with all $h_1, \ldots, h_m \geq 0$ by construction.

Università
della
Svizzera
italiana

Institute of
Computing
CI

Feasible Starting Basic Solution: Auxiliary Problem

The auxiliary problem is obtained by adding $m$ artificial variables $u_1, \ldots, u_m$ to the constraints:

$$a_{1,1}x_1 + a_{1,2}x_2 + \cdots + a_{1,n}x_n \pm s_1 + u_1 = h_1$$
$$\vdots$$
$$a_{m,1}x_1 + a_{m,2}x_2 + \cdots + a_{m,n}x_n \pm s_m + u_m = h_m$$

and by defining the new objective function:

$$z_{\mathsf{aux}} = u_1 + u_2 + \cdots + u_m.$$

The auxiliary problem is always a **minimization** problem. The starting feasible basic solution is given by the set of variables for which $z_{\mathsf{aux}} = 0$. If $z_{\mathsf{aux}}$ does not reach the value 0, then both the auxiliary problem and the original LP problem do not admit a feasible solution.

# Simplex Method: Minimization Example

Let us consider the following linear programming problem:

$$\begin{aligned}
\min \quad & z = 9x_1 + 11x_2 + 8x_3 \\
\text{s.t.} \quad & 2x_1 + x_2 + 3x_3 \geq 210 \\
& 3x_1 + 4x_2 + 2x_3 \geq 360 \\
& x_1,\, x_2,\, x_3 \geq 0
\end{aligned}$$

The problem is already in standard form for a minimization, so we can directly subtract the surplus variables to turn the inequalities into equality constraints.

Università
della
Svizzera
italiana

Institute of
Computing
CI

Simplex Method: Minimization Example

After subtracting the surplus variables, the problem becomes:

$$\begin{aligned}
\min \quad & z = 9x_1 + 11x_2 + 8x_3 \\
\text{s.t.} \quad & 2x_1 + x_2 + 3x_3 - s_1 = 210 \\
& 3x_1 + 4x_2 + 2x_3 - s_2 = 360 \\
& x_1, \, x_2, \, x_3 \geq 0; \;\; s_1, \, s_2 \geq 0
\end{aligned}$$

with the following quantities:

$$c = \underbrace{\begin{bmatrix} 9 \\ 11 \\ 8 \\ 0 \\ 0 \end{bmatrix}}_{5 \times 1}, \quad x = \underbrace{\begin{bmatrix} x_1 \\ x_2 \\ x_3 \\ s_1 \\ s_2 \end{bmatrix}}_{5 \times 1}, \quad A = \underbrace{\begin{bmatrix} 2 & 1 & 3 & -1 & 0 \\ 3 & 4 & 2 & 0 & -1 \end{bmatrix}}_{2 \times 5}, \quad h = \underbrace{\begin{bmatrix} 210 \\ 360 \end{bmatrix}}_{2 \times 1}.$$

We can split the matrices in the following basic variables:

$$c_B = \underbrace{\begin{bmatrix} 8 \\ 0 \end{bmatrix}}_{2\times 1}, \quad x_B = \underbrace{\begin{bmatrix} x_3 \\ s_1 \end{bmatrix}}_{2\times 1}, \quad B = \underbrace{\begin{bmatrix} 3 & -1 \\ 2 & 0 \end{bmatrix}}_{2\times 2}, \quad h = \underbrace{\begin{bmatrix} 210 \\ 360 \end{bmatrix}}_{2\times 1},$$

and nonbasic variables:

$$c_D = \underbrace{\begin{bmatrix} 9 \\ 11 \\ 0 \end{bmatrix}}_{3\times 1}, \quad x_D = \underbrace{\begin{bmatrix} x_1 \\ x_2 \\ s_2 \end{bmatrix}}_{3\times 1}, \quad D = \underbrace{\begin{bmatrix} 2 & 1 & 0 \\ 3 & 4 & -1 \end{bmatrix}}_{2\times 3}.$$

We obtain the following basic solution (remember to set $x_D = 0$):

$$x_B = B^{-1}h - B^{-1}Dx_D = \begin{bmatrix} 0 & 0.5 \\ -1 & 1.5 \end{bmatrix} \begin{bmatrix} 210 \\ 360 \end{bmatrix} = \begin{bmatrix} 180 \\ 330 \end{bmatrix},$$

which is feasible, since also the non-negativity constraint is satisfied. The corresponding value of the objective function is given by:

$$z = c_B^\intercal x_B = \begin{bmatrix} 8 & 0 \end{bmatrix} \begin{bmatrix} 180 \\ 330 \end{bmatrix} = 1440.$$

Is the solution optimal? Let us apply the simplex method to find it out.

Simplex Method: Minimization Example

We start by computing the reduced cost coefficients:

$$r_D = c_D^\mathsf{T} - c_B^\mathsf{T} B^{-1} D = \begin{bmatrix} 9 & 11 & 0 \end{bmatrix} - \begin{bmatrix} 8 & 0 \end{bmatrix} \begin{bmatrix} 1.5 & 2 & -0.5 \\ 2.5 & 5 & -1/5 \end{bmatrix} = \begin{bmatrix} -3 & -5 & 4 \end{bmatrix}.$$

According to the iterative rule, we pick the coefficient with the smallest value, since we are dealing with a minimization ($-5$ in this case). In other words, the entering variable will be $x_2$, since - according to the algorithm - it should improve the value of the objective function.

Which should be the departing variable?

Università

Computing
CI

Simplex Method: Minimization Example

We keep applying the iterative rule by computing the ratios for the second column:

$$\frac{B^{-1}h}{B^{-1}D} = \begin{bmatrix} 90 \\ 66 \end{bmatrix}$$

and by selecting the smallest positive value (in this case 66). The corresponding variable is $s_1$, which will be now leaving the basis.

How is our new system (basic and nonbasic variables) defined?

The basic variables are:

$$c_B = \underbrace{\begin{bmatrix} 8 \\ 11 \end{bmatrix}}_{2\times 1}, \quad x_B = \underbrace{\begin{bmatrix} x_3 \\ x_2 \end{bmatrix}}_{2\times 1}, \quad B = \underbrace{\begin{bmatrix} 3 & 1 \\ 2 & 4 \end{bmatrix}}_{2\times 2}, \quad h = \underbrace{\begin{bmatrix} 210 \\ 360 \end{bmatrix}}_{2\times 1}$$

while the nonbasic variables are:

$$c_D = \underbrace{\begin{bmatrix} 9 \\ 0 \\ 0 \end{bmatrix}}_{3\times 1}, \quad x_D = \underbrace{\begin{bmatrix} x_1 \\ s_1 \\ s_2 \end{bmatrix}}_{3\times 1}, \quad D = \underbrace{\begin{bmatrix} 2 & -1 & 0 \\ 3 & 0 & -1 \end{bmatrix}}_{2\times 3}$$

Simplex Method: Minimization Example

We obtain the following basic solution (remember to set $x_D = 0$):

$$x_B = B^{-1}h - B^{-1}Dx_D = \begin{bmatrix} 0.4 & -0.1 \\ -0.2 & 0.33 \end{bmatrix} \begin{bmatrix} 210 \\ 360 \end{bmatrix} = \begin{bmatrix} 48 \\ 66 \end{bmatrix}$$

which is again feasible, as guaranteed by the algorithm. The corresponding value of the objective function is given by:

$$z = c_B^{\mathsf{T}} x_B = \begin{bmatrix} 8 & 11 \end{bmatrix} \begin{bmatrix} 48 \\ 66 \end{bmatrix} = 1100.$$

The value is lower than the one obtained before (1440), so the objective function value is improving. Let us check if it is the optimal solution by computing the reduced cost coefficients.

# Simplex Method: Minimization Example

The reduced cost coefficients are given by:

$$r_D = c_D^\intercal - c_B^\intercal B^{-1} D = \begin{bmatrix} 9 & 0 & 0 \end{bmatrix} - \begin{bmatrix} 8 & 11 \end{bmatrix} \begin{bmatrix} 0.5 & -0.4 & 0.1 \\ 0.5 & 0.2 & -0.33 \end{bmatrix} = \begin{bmatrix} -0.5 & 1 & 2.5 \end{bmatrix}$$

The solution is still not optimal, since we have a negative reduced cost coefficient. The entering variable will be $x_1$, which corresponds to the only negative value $(-0.5)$.

Which should be the departing variable?

Università

CI | Simplex Method: Minimization Example

We keep applying the iterative rule by computing the ratios for the first column:

$$\frac{B^{-1}h}{B^{-1}D} = \begin{bmatrix} 96 \\ 132 \end{bmatrix}$$

and by selecting the smallest positive value (in this case 96). The corresponding variable is $x_3$, which will be now leaving the basis.

How is our new system (basic and nonbasic variables) defined?

The basic variables are:

$$c_B = \underbrace{\begin{bmatrix} 9 \\ 11 \end{bmatrix}}_{2 \times 1}, \quad x_B = \underbrace{\begin{bmatrix} x_1 \\ x_2 \end{bmatrix}}_{2 \times 1}, \quad B = \underbrace{\begin{bmatrix} 2 & 1 \\ 3 & 4 \end{bmatrix}}_{2 \times 2}, \quad h = \underbrace{\begin{bmatrix} 210 \\ 360 \end{bmatrix}}_{2 \times 1}$$

while the nonbasic variables are:

$$c_D = \underbrace{\begin{bmatrix} 8 \\ 0 \\ 0 \end{bmatrix}}_{3 \times 1}, \quad x_D = \underbrace{\begin{bmatrix} x_3 \\ s_1 \\ s_2 \end{bmatrix}}_{3 \times 1}, \quad D = \underbrace{\begin{bmatrix} 3 & -1 & 0 \\ 2 & 0 & -1 \end{bmatrix}}_{2 \times 3}$$

Simplex Method: Minimization Example

We obtain the following basic solution (remember to set $x_D = 0$):

$$x_B = B^{-1}h - B^{-1}Dx_D = \begin{bmatrix} 0.8 & -0.2 \\ -0.66 & 0.4 \end{bmatrix} \begin{bmatrix} 210 \\ 360 \end{bmatrix} = \begin{bmatrix} 96 \\ 18 \end{bmatrix}$$

which is again feasible, as guaranteed by the algorithm. The corresponding value of the objective function is given by:

$$z = c_B^\mathsf{T} x_B = \begin{bmatrix} 9 & 11 \end{bmatrix} \begin{bmatrix} 96 \\ 18 \end{bmatrix} = 1062.$$

We obtained an even lower value of the objective function ($1062 < 1100$). Can we still do better or we reached the optimal solution?

The reduced cost coefficients are given by:

$$r_D = c_D^{\intercal} - c_B^{\intercal} B^{-1} D = \begin{bmatrix} 9 & 0 & 0 \end{bmatrix} - \begin{bmatrix} 9 & 11 \end{bmatrix} \begin{bmatrix} 2 & -0.8 & 0.2 \\ -1 & 0.66 & -0.4 \end{bmatrix} = \begin{bmatrix} 1 & 0.6 & 2.6 \end{bmatrix}$$

All the reduced cost coefficients are positive and the algorithm stops: the simplex method converged to the optimal solution, given by:

$$x^* = \begin{bmatrix} 96 \\ 18 \\ 0 \end{bmatrix}, \text{ with } z^* = 1062.$$
